2 Generic programming in CGAL

Examples of Computational Geometry Algorithms

• Convex hulls, triangulations, Voronoi diagrams

(日)

- Emphasis on asymptotic complexity (Real-RAM model)
- Algorithms manipulating large numbers of geometric objects

CGAL: Software Architecture

General architecture: kernel, basic library, support library

Kernel of geometric primitives

Algorithms are logically split into:

- a combinatorial part (constructs a graph)
- a numerical part (makes use of coordinates)

The latter calls primitives gathered in the kernel:

- Basic objects: points, segments, lines, circles...
- Predicates: orientations, abscissa comparisons...
- Constructions: intersection, distance computations...

Kernel of geometric primitives

Example: Delaunay triangulation

Incremental algorithm in 2 steps: point location and update.

Point location: orientation(p, q, r) predicate, sign of:

$$\begin{vmatrix} 1 & px & py \\ 1 & qx & qy \\ 1 & rx & ry \end{vmatrix} = \begin{vmatrix} qx - px & qy - py \\ rx - px & ry - py \end{vmatrix}$$

Example: Delaunay triangulation

Incremental algorithm in 2 steps: point location and update.

Point location: orientation(p, q, r) predicate, sign of:

$$\begin{vmatrix} 1 & px & py \\ 1 & qx & qy \\ 1 & rx & ry \end{vmatrix} = \begin{vmatrix} qx - px & qy - py \\ rx - px & ry - py \end{vmatrix}$$

・ロト ・ 一下・ ・ ヨト ・ ヨト

3

Delaunay triangulation

Incremental algorithm in 2 steps: point location and update.

Update: in_circle(p, q, r, s) predicate, sign of:

$$\begin{vmatrix} 1 & px & py & px^2 + py^2 \\ 1 & qx & qy & qx^2 + qy^2 \\ 1 & rx & ry & rx^2 + ry^2 \\ 1 & sx & sy & sx^2 + sy^2 \end{vmatrix}$$

() < </p>

3

Delaunay triangulation

Incremental algorithm in 2 steps: point location and update.

Update: in_circle(p, q, r, s) predicate, sign of:

$$\begin{vmatrix} 1 & px & py & px^2 + py^2 \\ 1 & qx & qy & qx^2 + qy^2 \\ 1 & rx & ry & rx^2 + ry^2 \\ 1 & sx & sy & sx^2 + sy^2 \end{vmatrix}$$

Voronoi diagram of points

Voronoi diagram of line segments

Voronoi diagram of circles

ggae

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ● ●

Robustness problems

Algorithms rely on mathematical theorems, like:

ggae

Robustness

Example where floating-point geometry differs from real geometry: orientation of almost collinear points.

[Kettner, Mehlhorn, Schirra, P., Yap, ESA'04]

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● ● ● ●

Potential consequences on algorithms

Slightly wrong result

Completely wrong result

- The algorithm stops on a invalid assertion
- The algorithm loops forever

Potential consequences on algorithms

Slightly wrong result

- Completely wrong result
- The algorithm stops on a invalid assertion
- The algorithm loops forever

・ ロ ト ・ 雪 ト ・ ヨ ト ・

.....

Robustness: solutions

• Case-by-case treatment: painful, error prone, not mathematically nice

Use exact predicates (Exact Geometric Computing)

Remarks

- Floating-point fails on [almost] degenerate cases.
- These cases happen more of less often in practice.

Remarks

- Floating-point fails on [almost] degenerate cases.
- These cases happen more of less often in practice.

Geometric primitives are parameterized by the arithmetic.

- Multiple precision integers
- Multiple precision rationals
- Multiple precision floating-point
- Interval arithmetic (with double or MP bounds)

Algebraic numbers:

- Numerical evaluation with separation bounds
- Polynomials, Sturm, resultants...

[CORE, LEDA] [CGAL, SYNAPS]

Filtered predicates

Speed up exact predicates using a filter:

- floating-point evaluation with a certificate
- multiple precision only when needed

Examples

 interval arithmetic (dynamic filters), [Burnikel, Funke, Seel – Brönnimann, Burnikel, P.'98]

or static code analysis (static filters)

[Fortune'93... Melquiond, P.'05]

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Programming aspects:

- automatic generation of filtered predicates
- cascading/pipelining various methods

Filtered number types

DAG of the operations in memory, e.g.: $\sqrt{x} + \sqrt{y} - \sqrt{x + y + 2\sqrt{xy}}$

Approximation and iterative precision refinement, on demand $rac{1}{2}$, $rac{1}{2}$, $rac{1}{2}$, $rac{1}{2}$,

Filtered predicates: benchmarks

Running time of a 3D Delaunay triangulation.

	R5	E	M	В	D
double	40.6	41.0	43.7	50.3	loops
MPF	3,063	2,777	3,195	3,472	214
Interval + MPF	137.2	133.6	144.6	165.1	15.8
semi static + Interval + MPF	51.8	61.0	59.1	93.1	8.9
almost static + semi static					
+ Interval + MPF	44.4	55.0	52.0	87.2	8.0
Shewchuk's predicates	57.9	57.5	62.8	71.7	7.2
CORE Expr	570	3520	1355	9600	173
LEDA real	682	640	742	850	125
Lazy_exact_nt <mpf></mpf>	705	631	726	820	67

An important criteria: failure rate of filters. User interface in CGAL: choice of different kernels.

Filtered geometric constructions

Additional difficulty: storage of geometric objects in memory Bonus: regrouping computations, and less memory

Algorithms and traits classes

Generic programming: algorithms are decoupled from the data structures and the numerics. Similarly to the C++ STL.

Algorithms are parameterized (templates) by geometric traits classes which provide:

- types of the objets manipulated by the algorithm: Point_2, Tetrahedron_3...
- predicates that the algorithm applies to objets: Orientation_2, Side_of_oriented_sphere_3...
- constructions : Construct_mid_point_2, Construct_circumcenter_3, Compute_squared_length_2...

These last two are provided under the form of function objects.

Algorithms and traits classes

Generic programming: algorithms are decoupled from the data structures and the numerics. Similarly to the C++ STL.

Algorithms are parameterized (templates) by geometric traits classes which provide:

Kernel interface

CGAL geometric algorithms are parameterized by a geometric traits.

```
class Triangulation_3;
```

It provides a (attempted minimal) set of types and functions for the geometry :

Nested Type	Requirements
Point_3	Assignable, DefaultConstructible
Segment_3	Assignable, DefaultConstructible
Orientation_3	Function object taking 4 Point_3, returning enum
Circumcenter_3	

Kernels

The kernel can be used as a model for the geometric traits class parameter in numerous algorithms.

Basic kernels, parameterized by number types: Cartesian<FT> Homogeneous<RT>

Ex : Triangulation_3<Cartesian<double>>

Cartesian<double> is a model of the TriangulationTraits_3 concept.

The kernel can be used as a model for the geometric traits class parameter in numerous algorithms.

Basic kernels, parameterized by number types: Cartesian<FT> Homogeneous<RT>

Ex : Triangulation_3<Cartesian<double>>

Cartesian<double> is a model of the TriangulationTraits_3 concept.

The kernel can be used as a model for the geometric traits class parameter in numerous algorithms.

Basic kernels, parameterized by number types: Cartesian<FT> Homogeneous<RT>

Filtered predicates generator using C++ exceptions: CGAL::Filtered_predicate<>

CGAL::Filtered_kernel< ${\it K}$ > provides some predicates based on static filtering, and all others dynamic (IA).

Recommended kernels: CGAL::Exact_predicates_exact_constructions_kernel CGAL::Exact_predicates_inexact_constructions_kernel

Filtered kernels

Internal tools:

Interval arithmetic: CGAL::Interval_nt, boost::interval

Filtered predicates generator using C++ exceptions: CGAL::Filtered_predicate<>

CGAL::Filtered_kernel< ${\cal K}$ > provides some predicates based on static filtering, and all others dynamic (IA).

Recommended kernels: CGAL::Exact_predicates_exact_constructions_kernel CGAL::Exact_predicates_inexact_constructions_kernel

C-3C-36-35-2

(日) (日) (日) (日) (日) (日) (日)

Example 1

```
template < typename K >
struct My orientation 2
 typedef typename K::RT RT;
  typedef typename K:: Point 2 Point 2;
 CGAL :: Orientation
  operator()(const Point_2 &p, const Point_2 &q,
             const Point 2 &r) const
   RT prx = p.x() - r.x(); RT pry = p.y() - r.y();
   RT qrx = q.x() - r.x(); RT qry = q.y() - r.y();
    return static_cast <CGAL:: Orientation > (
            CGAL::sign( prx*qry - qrx*pqy ) );
};
```

Example 2

// We use it:

typedef CGAL::Cartesian<double> Kernel;

Kernel:: Point_2 p(1, 2), q(2, 3), r(4, 5);

My_orientation_2 <Kernel> orientation;

CGAL:: Orientation ori = orientation(p, q, r);

return 0:

Using Filtered_predicate

C++ is not everything: what about other languages?

We have started to write CGAL wrappers in other languages:

- Scilab, Matlab: not object-oriented, complete rethinking needed
- Python, Java: object-oriented, similar interface and paradigms

Python interface

Python is:

- object-oriented (syntax similar to C++)
- interpreted (precompiled, no templates)
- general purpose, used more and more for scientific tasks
- C++ wrappers generators exist
- cgal-python has already wrapped several CGAL packages http://cgal-python.gforge.inria.fr/

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

Java interface

Java is:

- as important as C++
- simpler (garbage collection...)
- syntax is in the same family as C++
- status: the 2D triangulation class has been wrapped.

Conclusion

Thank you for your attention.
